

Announcements

- ❖ **Project 2: Multi-agent Search**
 - ❖ Due Sunday June 20 at 11:59pm.
- ❖ **Homework 4: RL**
 - ❖ Has been released! Due Wed. June 23 at 11:59pm.
- ❖ **Midterm Exam**
 - ❖ June 25, 12:10pm-1:50pm
 - ❖ Covers everything, CSP included.
- ❖ **Recitations**
 - ❖ June 22, 1pm-3pm; followed by OH

Ve492: Introduction to Artificial Intelligence

Constraint Satisfaction Problems I

Paul Weng

UM-SJTU Joint Institute

Slides adapted from <http://ai.berkeley.edu>, AIMA, UM, CMU

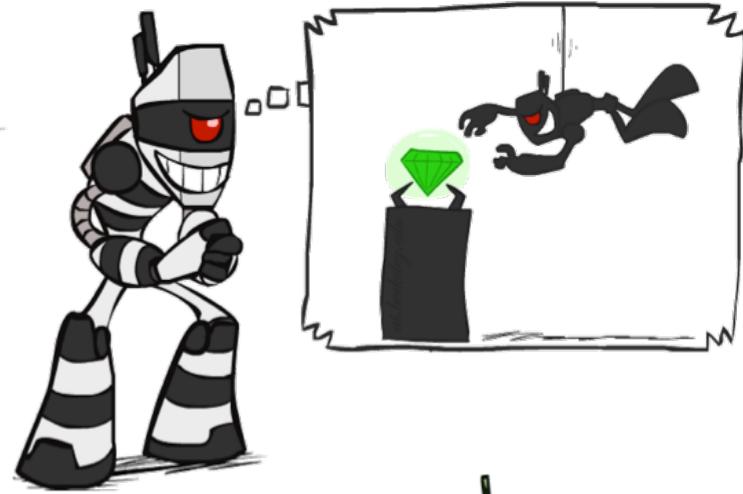

What have we learned so far?

- ❖ Search and planning
 - ❖ Define a state space, goal test; Find path from start to goal
- ❖ Game trees
 - ❖ Define utilities; Find path from start that maximizes utility
- ❖ Decision theory and game theory
 - ❖ Foundation for MEU; Basic concepts in game theory
- ❖ MDPs
 - ❖ Define rewards, utility = (discounted) sum of rewards
 - ❖ Find policy that maximizes utility
- ❖ Reinforcement learning
 - ❖ Just like MDPs, only T and / or R are not known in advance
- ❖ Today: constraint satisfaction
 - ❖ Find solution that satisfies constraints; Not just for finding a sequential plan

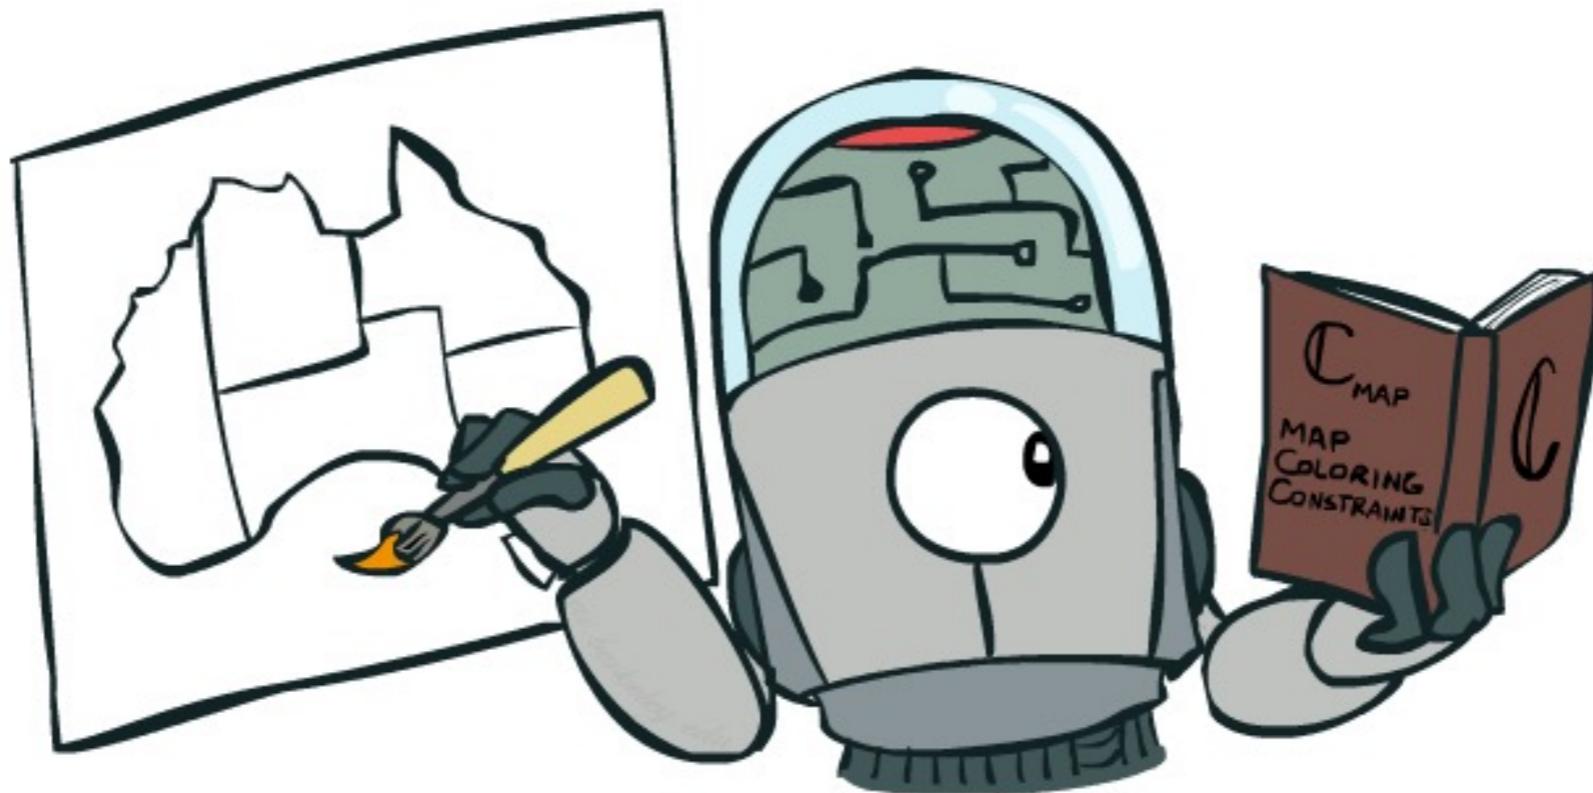

What is Search For?

- ❖ Assumptions about the world: a single agent, deterministic actions, fully observed state, discrete state space
- ❖ Planning: sequences of actions
 - ❖ The path to the goal is the important thing
 - ❖ Paths have various costs, depths
 - ❖ Heuristics give problem-specific guidance
- ❖ Identification: assignments to variables
 - ❖ The goal itself is important, not the path
 - ❖ All paths at the same depth (for some formulations)
 - ❖ CSPs are specialized for identification problems

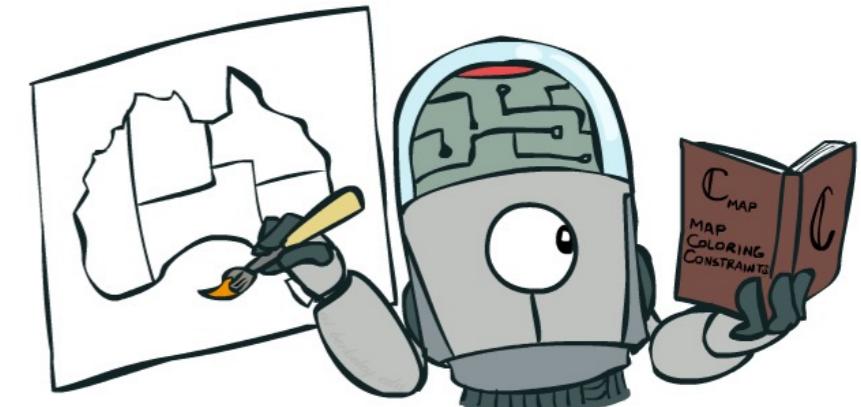

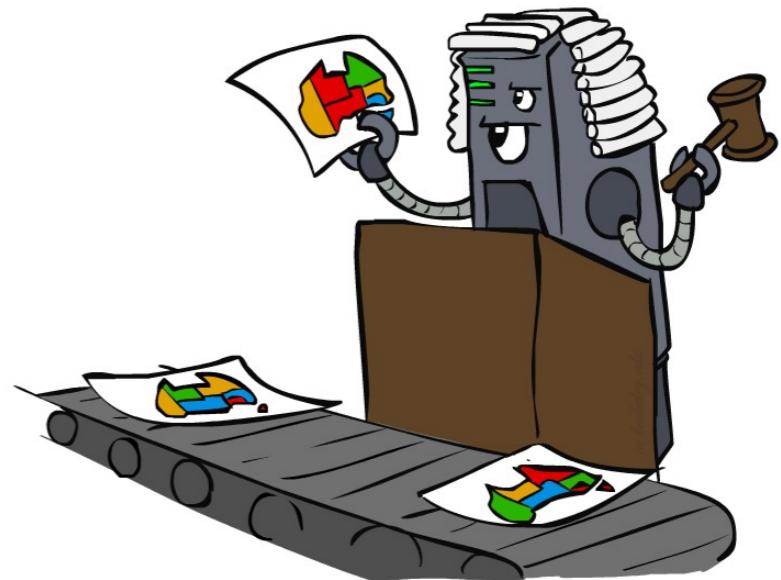

Constraint Satisfaction Problems

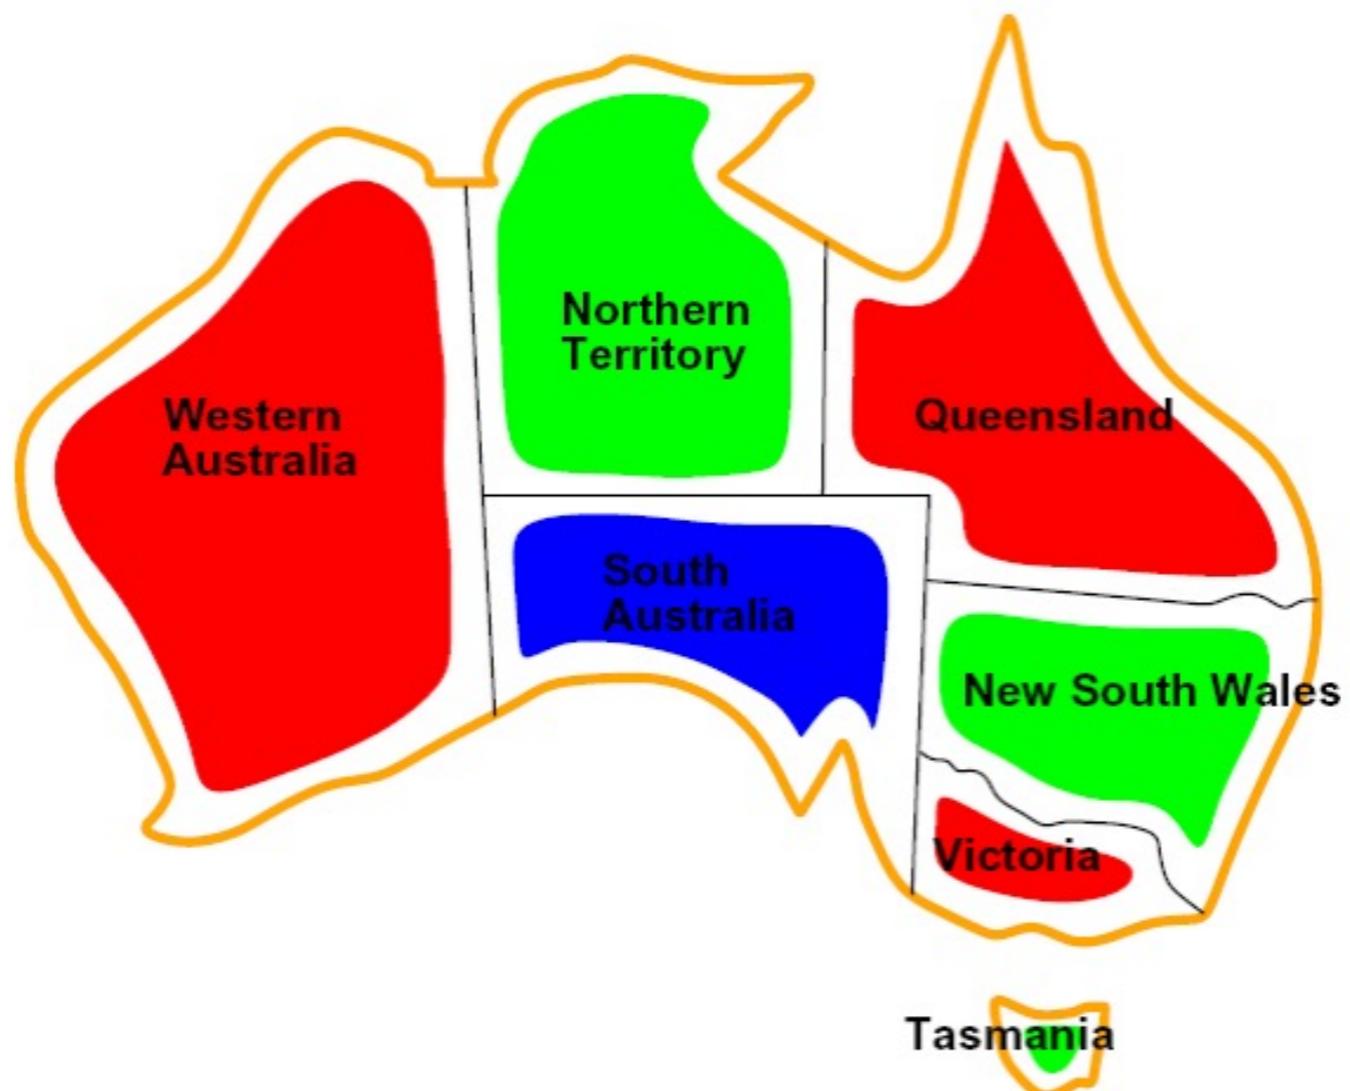

Constraint Satisfaction Problems

- ❖ Standard search problems:
 - ❖ State is a “black box”: arbitrary data structure
 - ❖ Goal test can be any function over states
 - ❖ Successor function can also be anything
- ❖ Constraint satisfaction problems (CSPs):
 - ❖ A special subset of search problems
 - ❖ State is defined by variables X_i with values from a domain D (sometimes D depends on i)
 - ❖ Goal test is a set of constraints specifying allowable combinations of values for subsets of variables
- ❖ Simple example of a *formal representation language*
- ❖ Allows useful general-purpose algorithms with more power than standard search algorithms

CSP Examples

Example: Map Coloring

- ❖ Variables: WA, NT, Q, NSW, V, SA, T

- ❖ Domains: $D = \{\text{red, green, blue}\}$

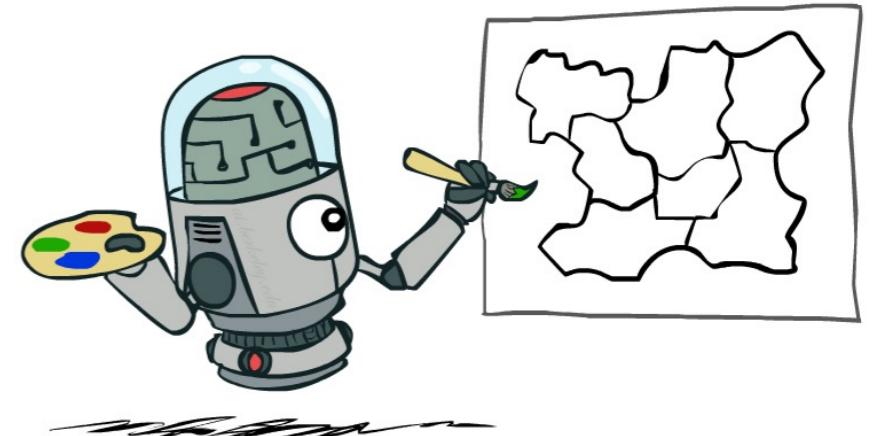

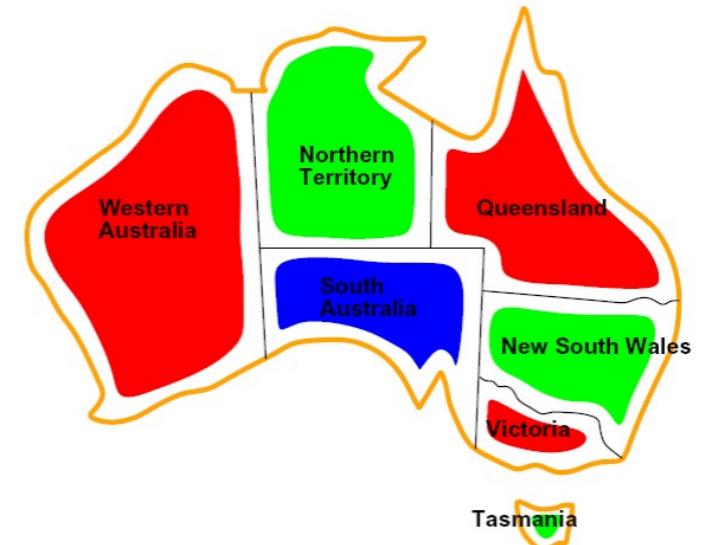

- ❖ Constraints: adjacent regions must have different colors

Implicit: $\text{WA} \neq \text{NT}$

Explicit: $(\text{WA}, \text{NT}) \in \{(\text{red, green}), (\text{red, blue}), \dots\}$

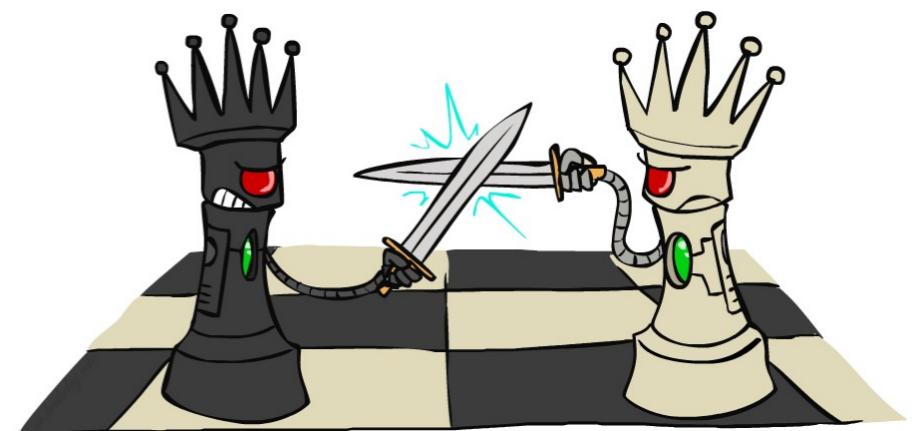

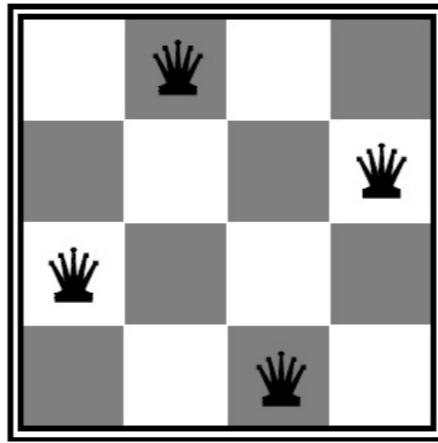

- ❖ Solutions are assignments satisfying all constraints, e.g.:

$\{\text{WA=red, NT=green, Q=red, NSW=green, V=red, SA=blue, T=green}\}$

Example: N-Queens

- ❖ Formulation 1:
 - ❖ Variables: X_{ij}
 - ❖ Domains: $\{0, 1\}$
 - ❖ Constraints

$$\forall i, j, k \quad (X_{ij}, X_{ik}) \in \{(0,0), (0,1), (1,0)\}$$

$$\forall i, j, k \quad (X_{ij}, X_{kj}) \in \{(0,0), (0,1), (1,0)\}$$

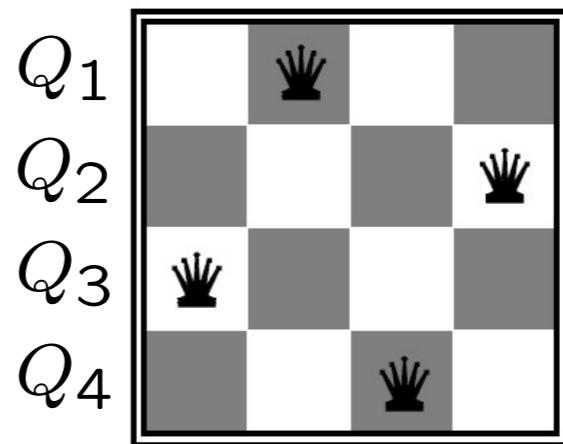

$$\sum_{i,j} X_{ij} = N$$

$$\forall i, j, k \quad (X_{ij}, X_{i+k, j+k}) \in \{(0,0), (0,1), (1,0)\}$$

$$\forall i, j, k \quad (X_{ij}, X_{i+k, j-k}) \in \{(0,0), (0,1), (1,0)\}$$

Example: N-Queens

- ❖ Formulation 2:
 - ❖ Variables: Q_k
 - ❖ Domains: $\{1, 2, 3, \dots, N\}$
 - ❖ Constraints:

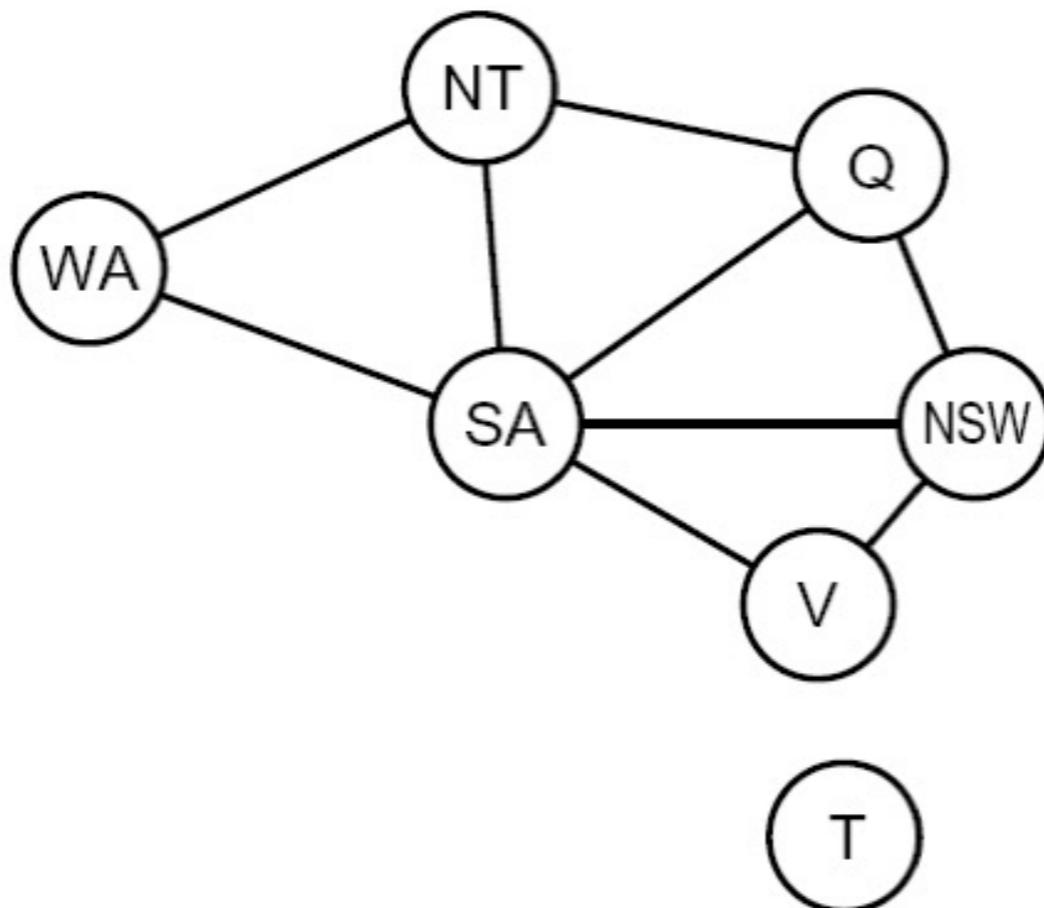

Implicit: $\forall i, j \text{ non-threatening}(Q_i, Q_j)$

Explicit: $(Q_1, Q_2) \in \{(1, 3), (1, 4), \dots\}$

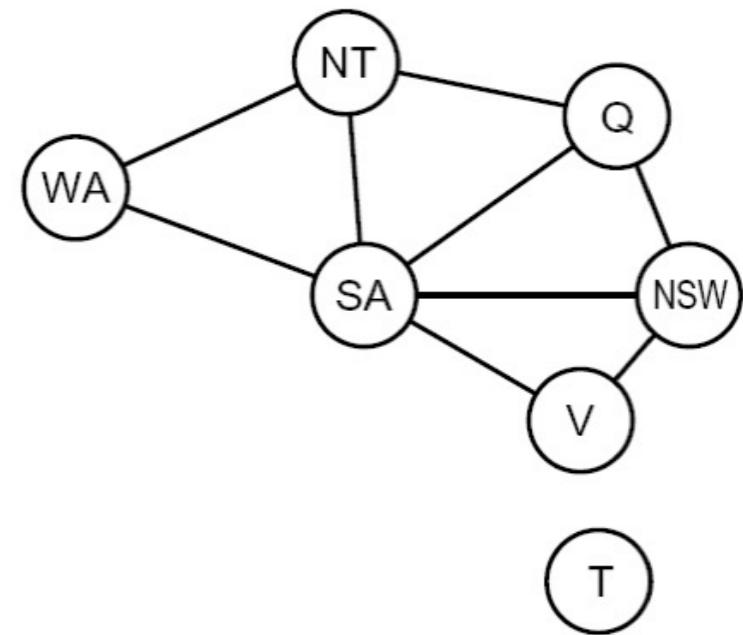

...

Constraint Graphs

Constraint Graphs

- ❖ Binary CSP: each constraint relates (at most) two variables
- ❖ Binary constraint graph: nodes are variables, arcs show constraints
- ❖ General-purpose CSP algorithms use the graph structure to speed up search. E.g., Tasmania is an independent subproblem!
- ❖ Example: [CSP solver](#)

Example: Cryptarithmetic

- ❖ **Variables:**

$F \ T \ U \ W \ R \ O \ X_1 \ X_2 \ X_3$

- ❖ **Domains:**

$\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$

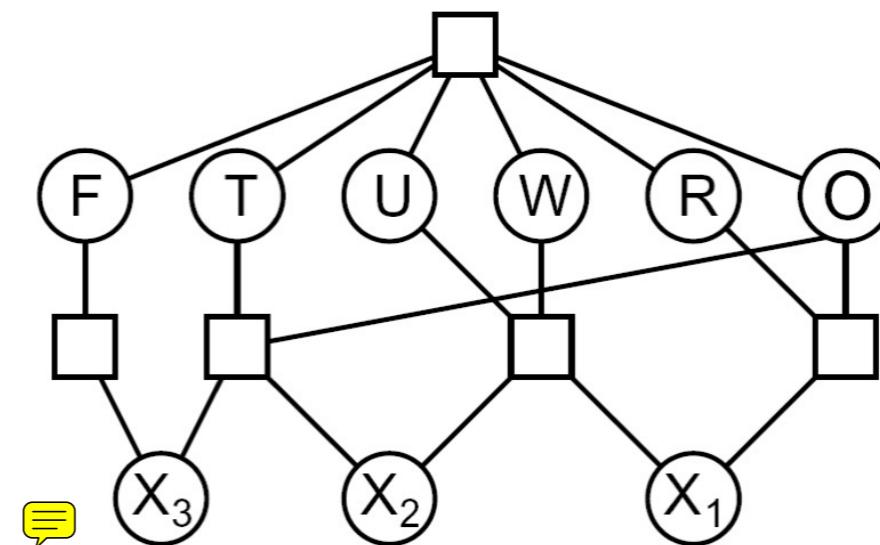

- ❖ **Constraints:**

$\text{alldiff}(F, T, U, W, R, O)$

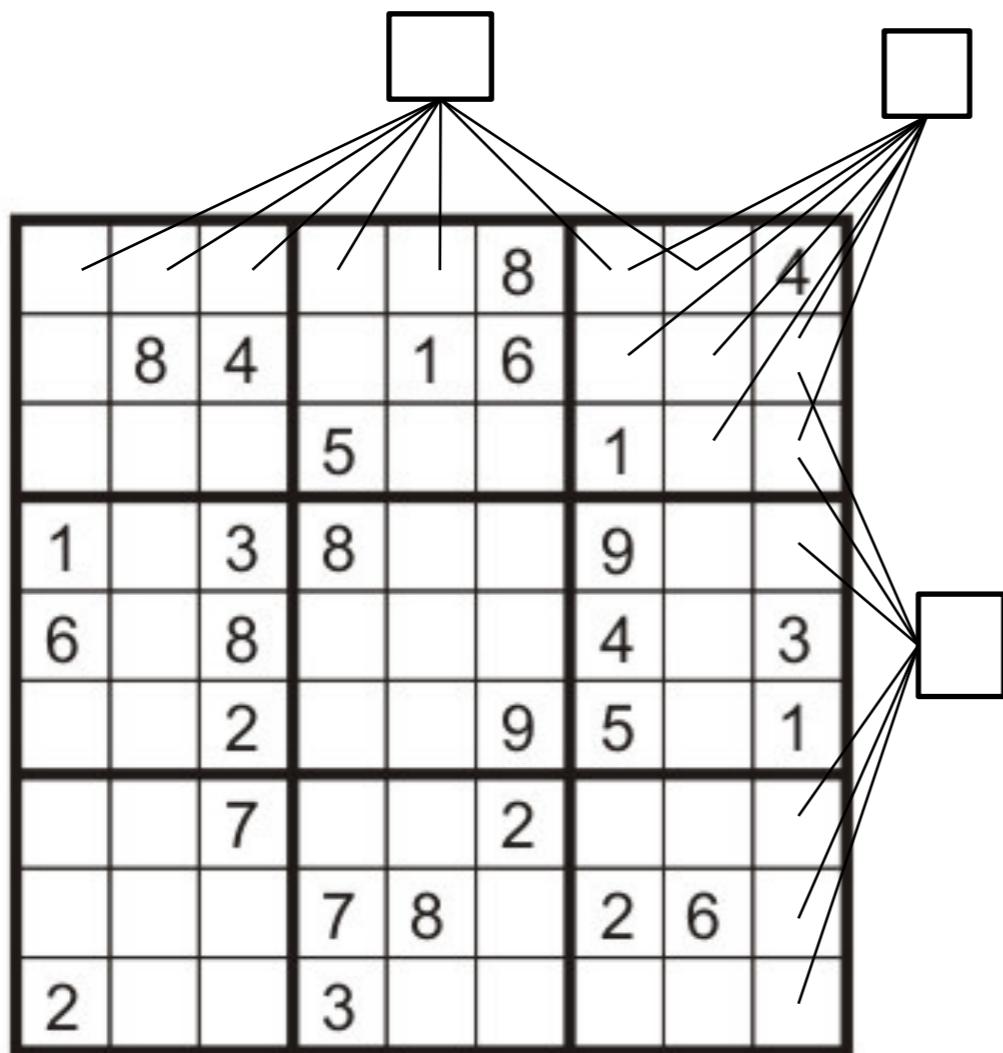

$$O + O = R + 10 \cdot X_1$$

...

$$\begin{array}{r} & x_3 & x_2 & x_1 \\ & T & W & O \\ + & T & W & O \\ \hline & F & O & U & R \end{array}$$

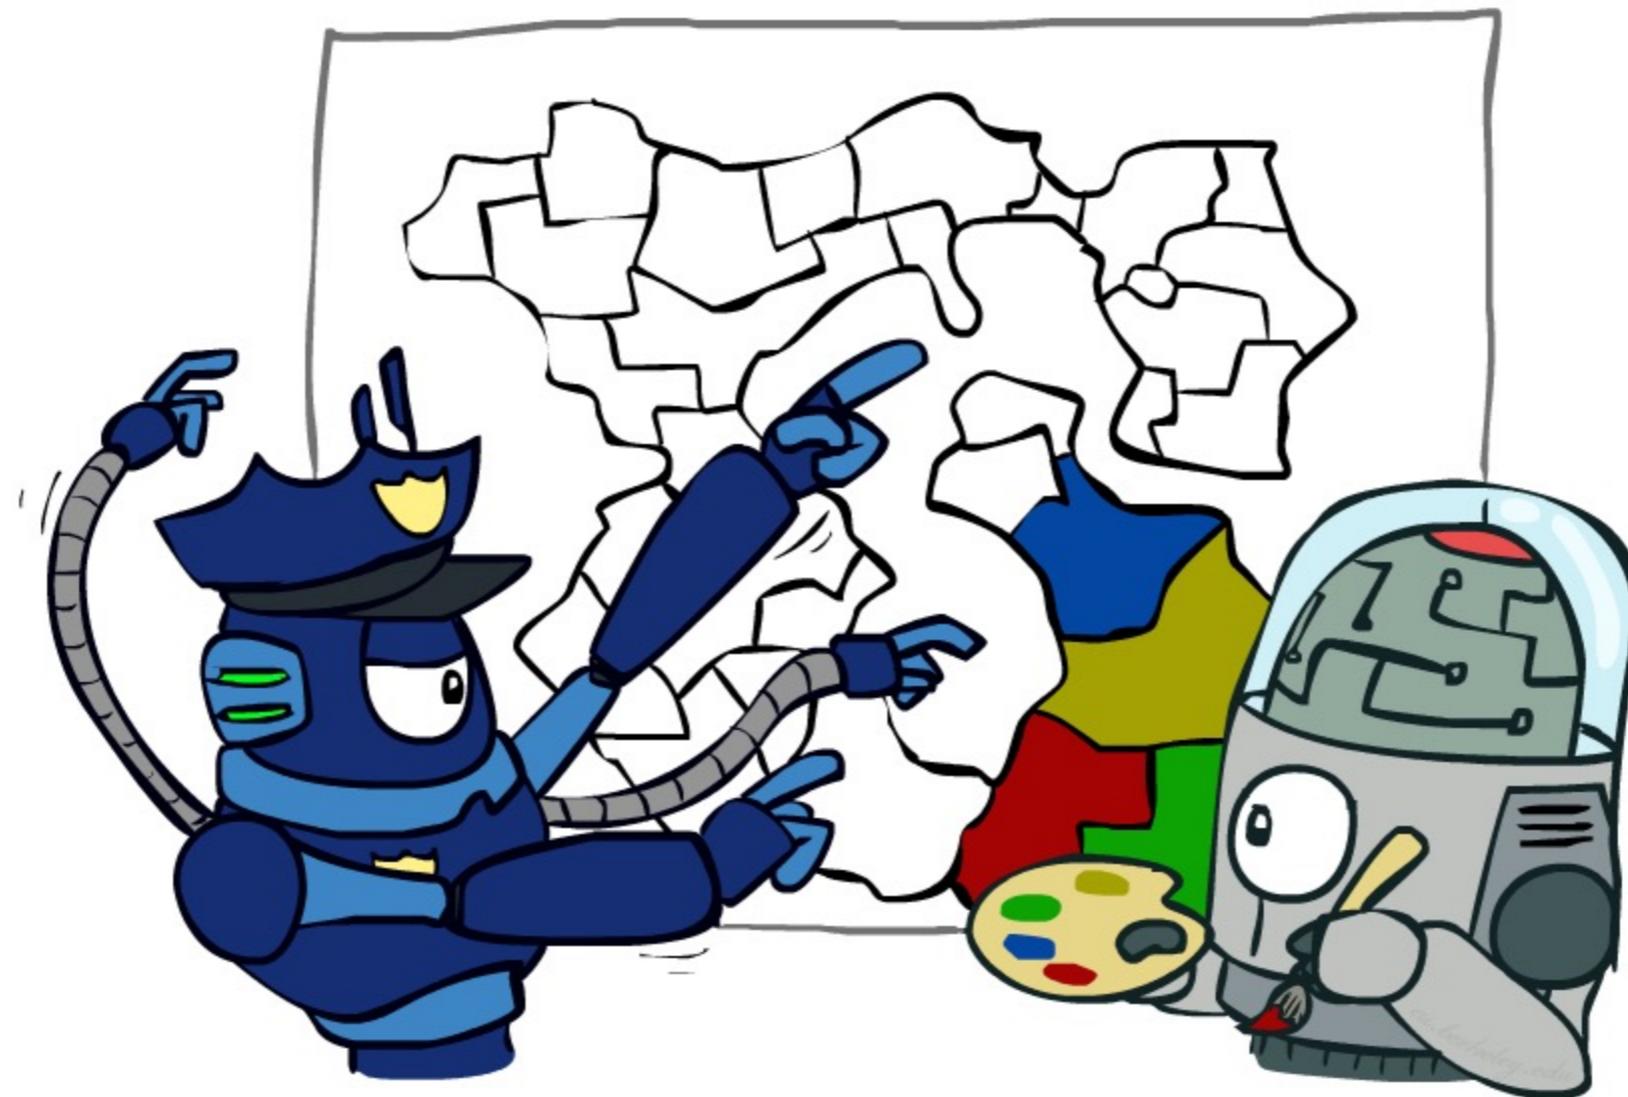

Example: Sudoku

- ❖ **Variables:**
Each (open) square
- ❖ **Domains:**
 $\{1,2,\dots,9\}$
- ❖ **Constraints:**
 - 9-way alldiff for each column
 - 9-way alldiff for each row
 - 9-way alldiff for each region
 - (or can have a bunch of pairwise inequality constraints)

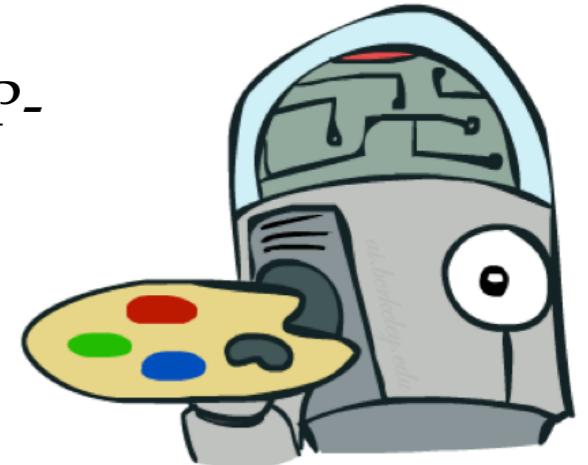

Varieties of CSPs and Constraints

Varieties of CSPs

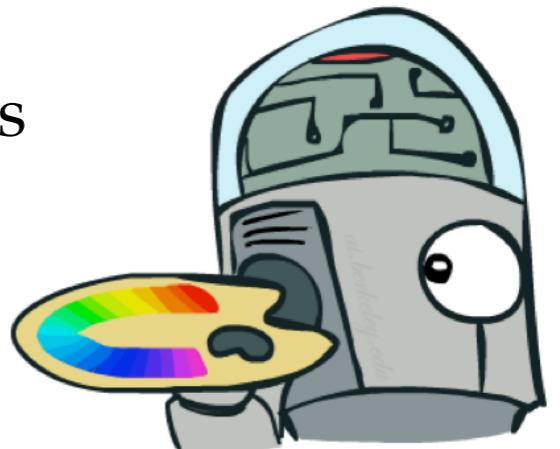

❖ Discrete Variables

- ❖ Finite domains
 - ❖ Size d means $O(d^n)$ complete assignments
 - ❖ E.g., Boolean CSPs, including Boolean satisfiability (NP-complete)
- ❖ Infinite domains (integers, strings, etc.)
 - ❖ E.g., job scheduling, variables are start/end times for each job
 - ❖ Linear constraints solvable, nonlinear undecidable

❖ Continuous variables

- ❖ E.g., start/end times for Hubble Telescope observations
- ❖ Linear constraints solvable in polynomial time by LP methods (see Ve555 for a bit of this theory)

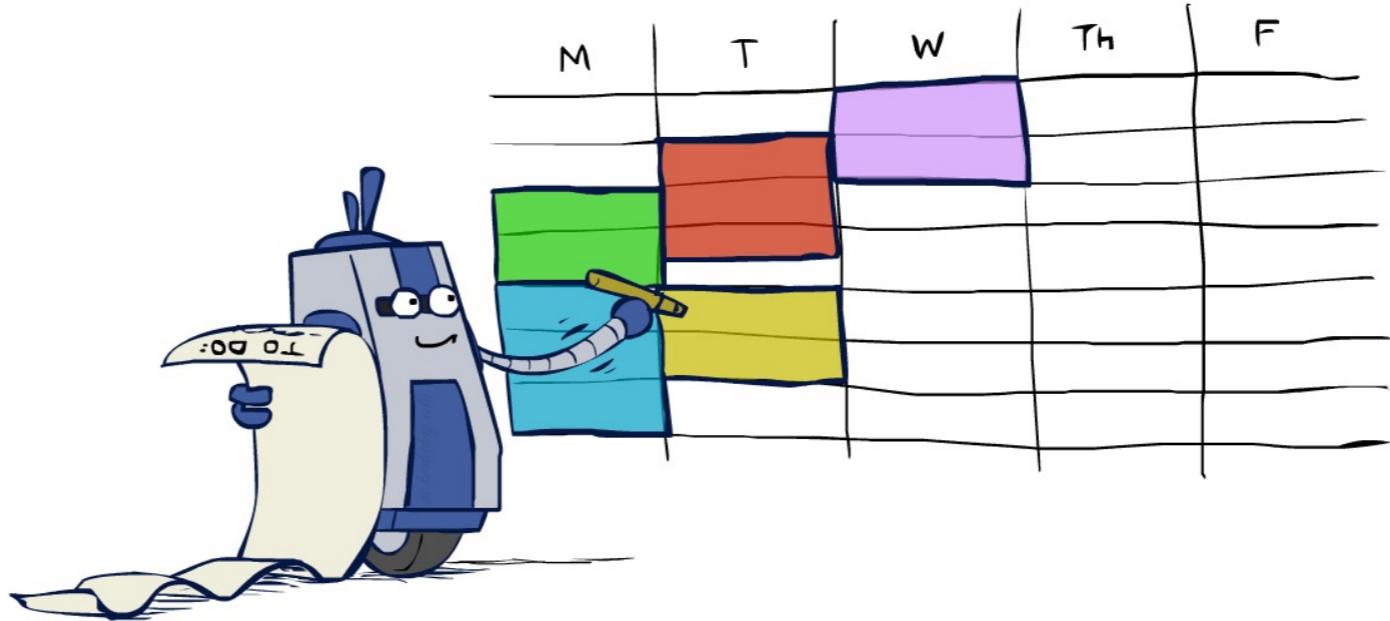

Varieties of Constraints

- ❖ Varieties of Constraints
 - ❖ Unary constraints involve a single variable (equivalent to reducing domains), e.g.:
 $SA \neq \text{green}$
 - ❖ Binary constraints involve pairs of variables, e.g.:
 $SA \neq WA$
 - ❖ Higher-order constraints involve 3 or more variables:
e.g., cryptarithmic column constraints
- ❖ Preferences (soft constraints):
 - ❖ E.g., red is better than green
 - ❖ Often representable by a cost for each variable assignment
 - ❖ Gives constrained optimization problems
 - ❖ (We'll ignore these until we get to Bayes' nets)

Real-World CSPs

- ❖ Assignment problems: e.g., who teaches what class
- ❖ Timetabling problems: e.g., which class is offered when and where?
- ❖ Hardware configuration
- ❖ Transportation scheduling
- ❖ Factory scheduling
- ❖ Circuit layout
- ❖ Fault diagnosis
- ❖ ... lots more!

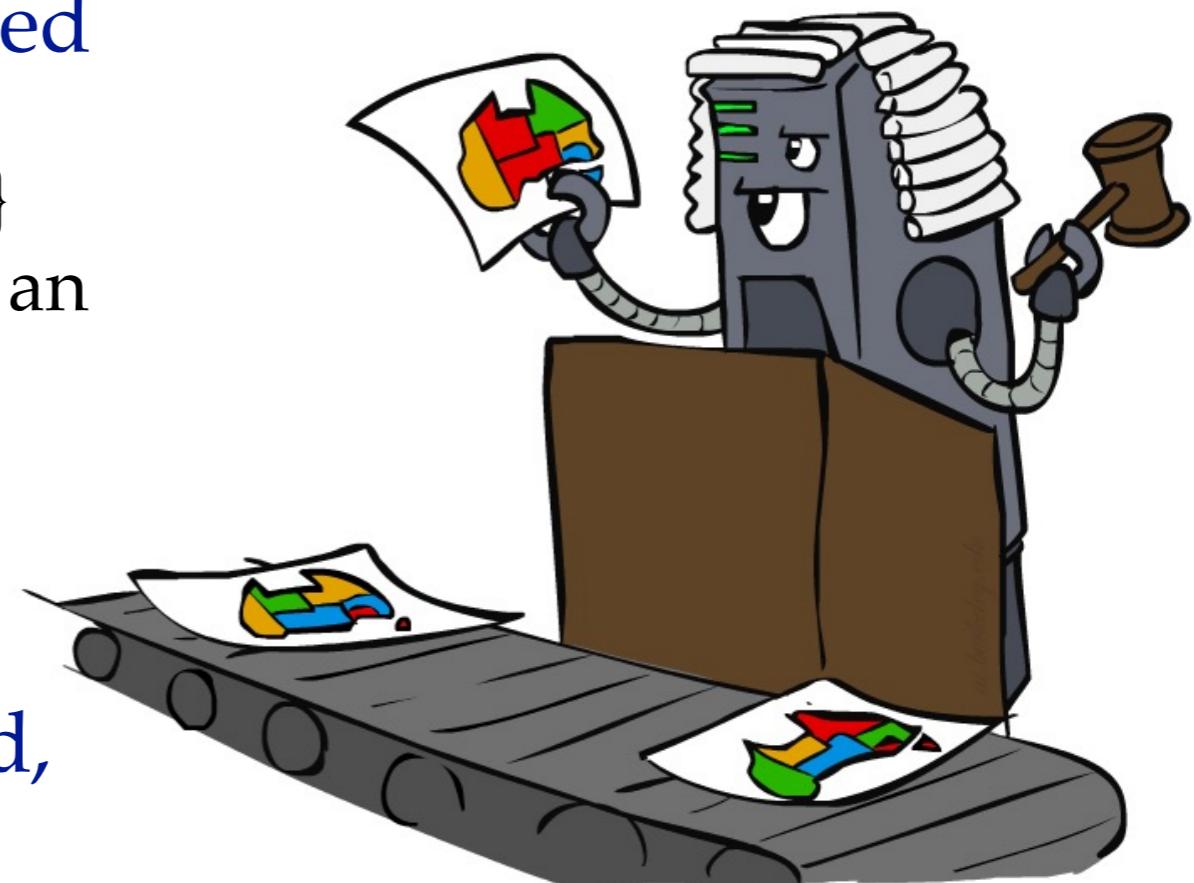

- ❖ Many real-world problems involve real-valued variables...

Solving CSPs

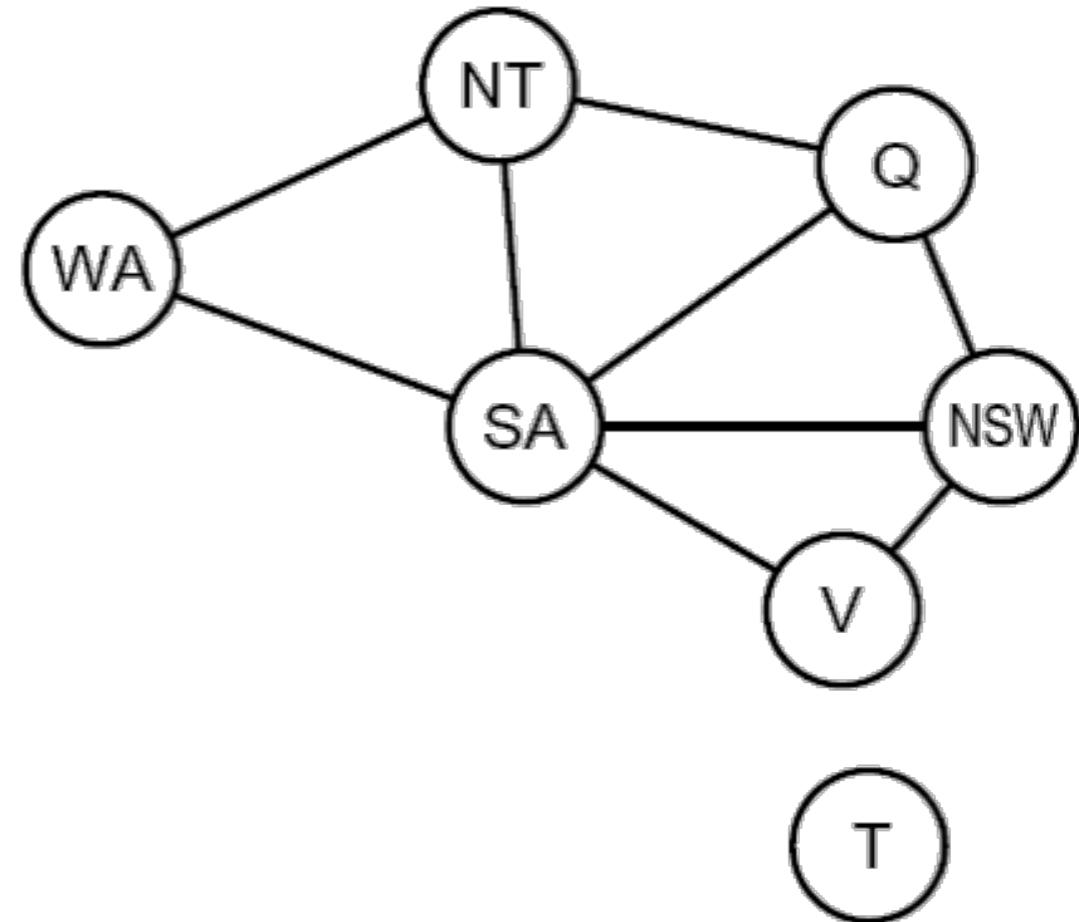

Standard Search Formulation

- ❖ Standard search formulation of CSPs
- ❖ States defined by the values assigned so far (partial assignments)
 - ❖ Initial state: the empty assignment, {}
 - ❖ Successor function: assign a value to an unassigned variable
 - ❖ Goal test: the current assignment is complete and satisfies all constraints
- ❖ We'll start with the straightforward, naïve approach, then improve it

Search Methods

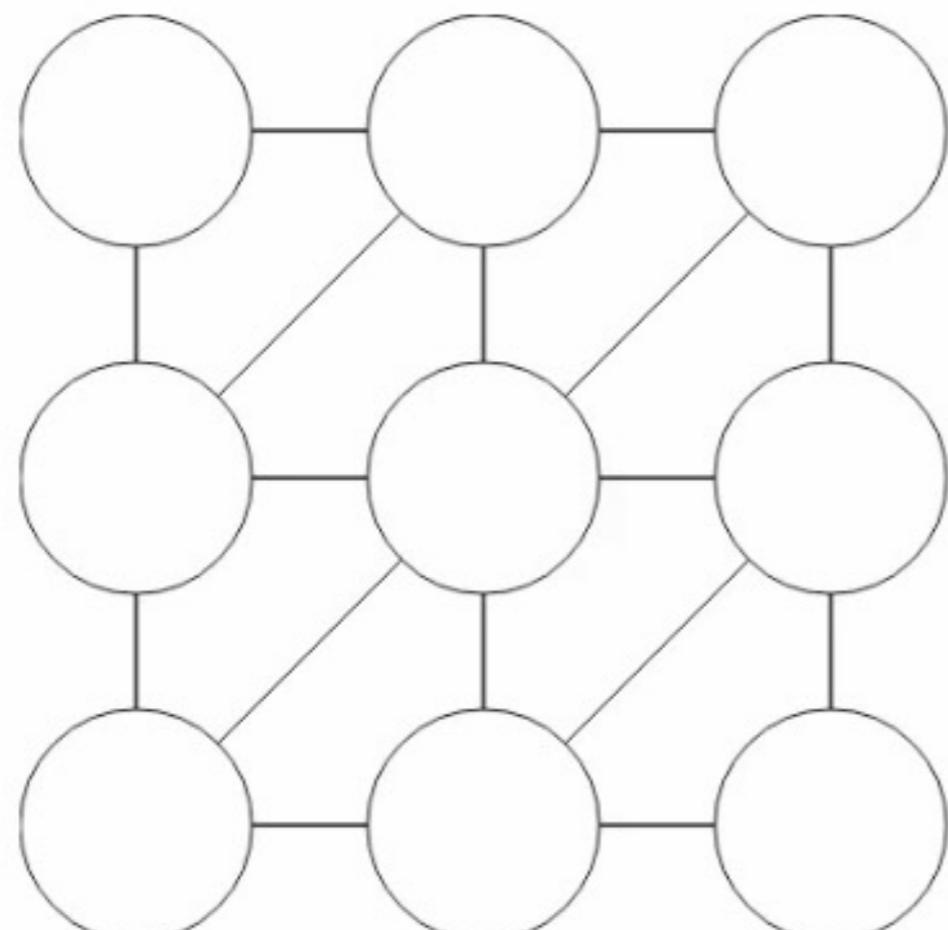

- ❖ What would BFS do?

- ❖ What would DFS do?

- ❖ What problems does naïve search have?

Backtracking Search

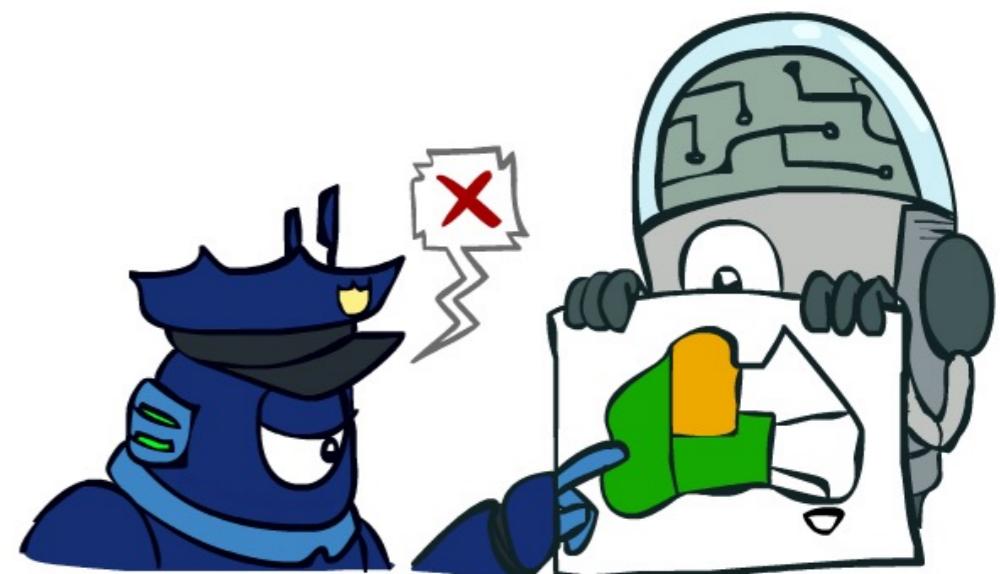

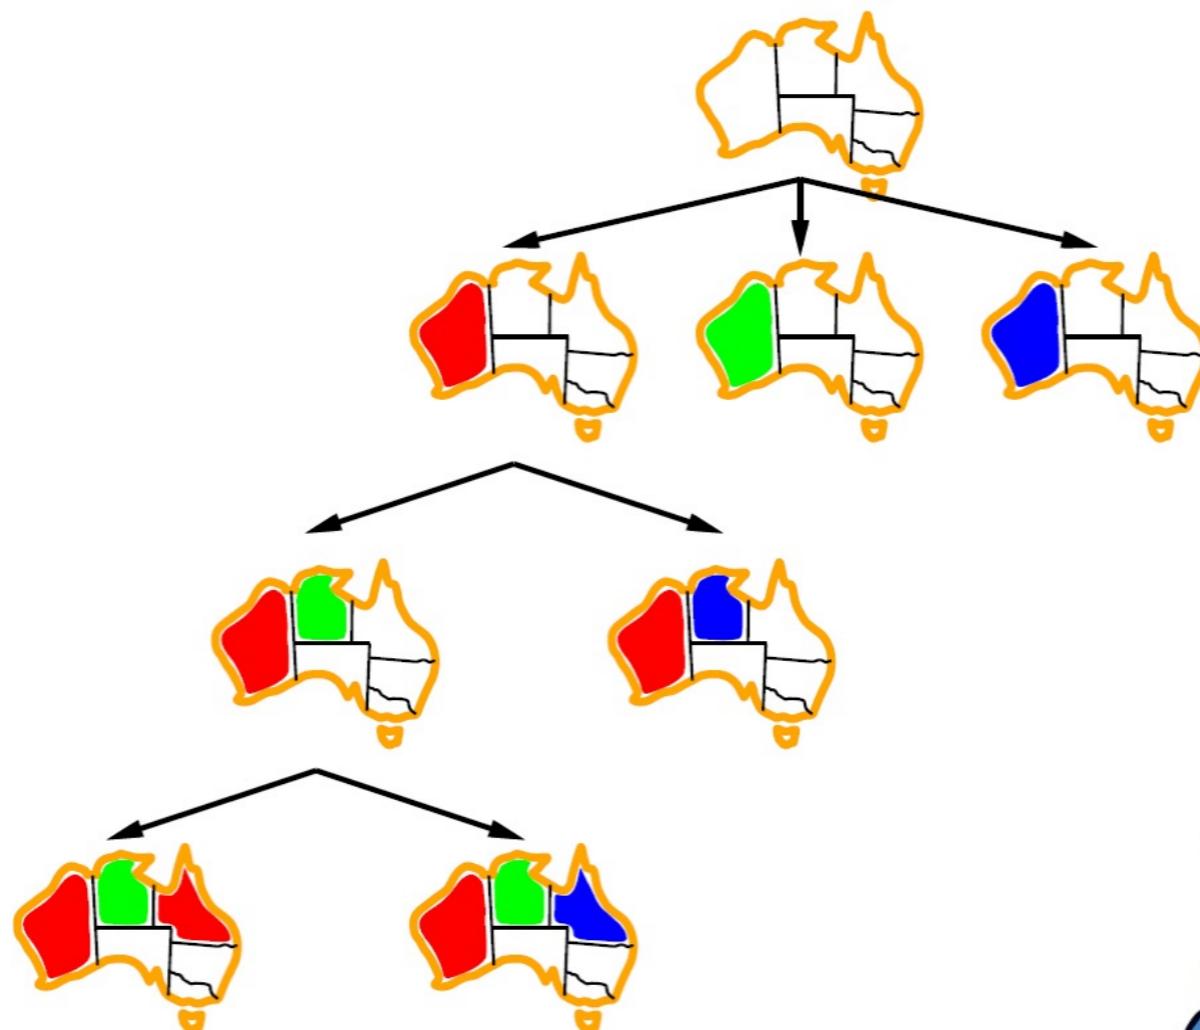

Backtracking Search

- ❖ Backtracking search is the basic uninformed algorithm for solving CSPs
- ❖ Idea 1: One variable at a time
 - ❖ Variable assignments are commutative, so fix ordering
 - ❖ I.e., [WA = red then NT = green] same as [NT = green then WA = red]
 - ❖ Only need to consider assignments to a single variable at each step
- ❖ Idea 2: Check constraints as you go
 - ❖ I.e. consider only values which do not conflict previous assignments
 - ❖ Might have to do some computation to check the constraints
 - ❖ “Incremental goal test”
- ❖ Depth-first search with these two improvements is called *backtracking search* (not the best name)
- ❖ Can solve n-queens for $n \approx 25$

Backtracking Example

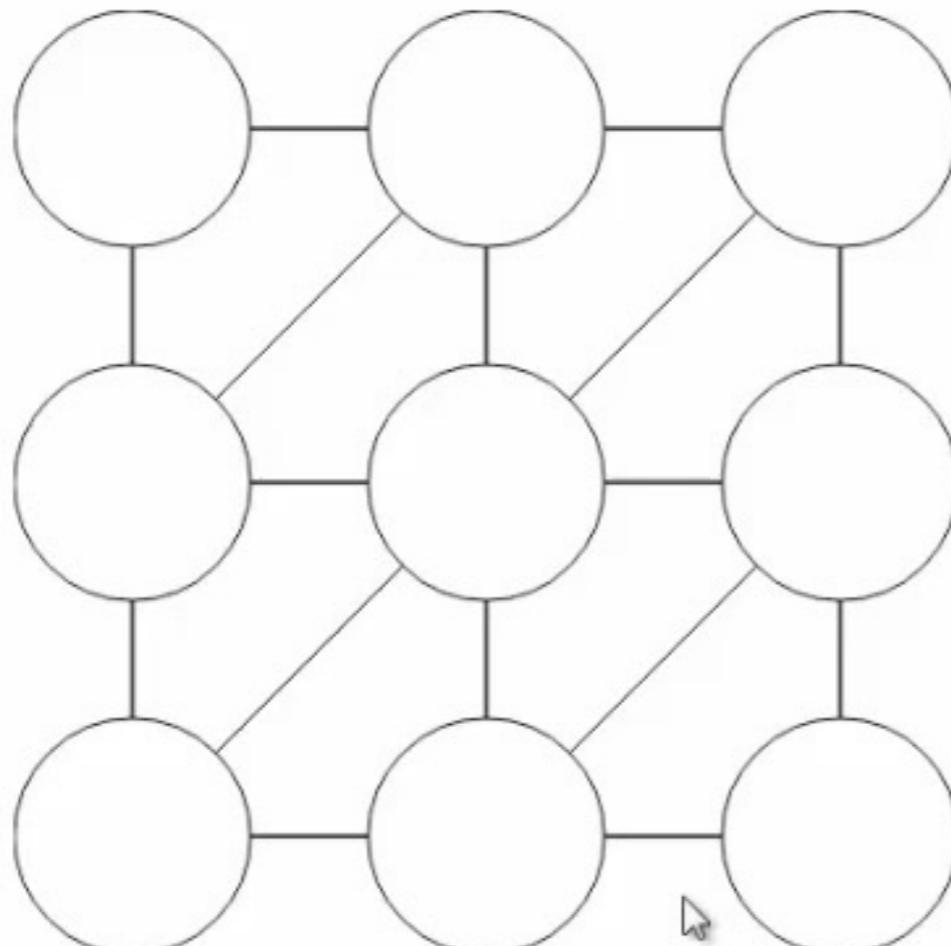

Backtracking Search

```
function BACKTRACKING-SEARCH(csp) returns solution/failure
    return RECURSIVE-BACKTRACKING({ }, csp)
function RECURSIVE-BACKTRACKING(assignment, csp) returns soln/failure
    if assignment is complete then return assignment
    var  $\leftarrow$  SELECT-UNASSIGNED-VARIABLE(VARIABLES[csp], assignment, csp)
    for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do
        if value is consistent with assignment given CONSTRAINTS[csp] then
            add {var = value} to assignment
            result  $\leftarrow$  RECURSIVE-BACKTRACKING(assignment, csp)
            if result  $\neq$  failure then return result
            remove {var = value} from assignment
    return failure
```

- ❖ Backtracking = DFS + variable-ordering + fail-on-violation
- ❖ What are the choice points?

Improving Backtracking

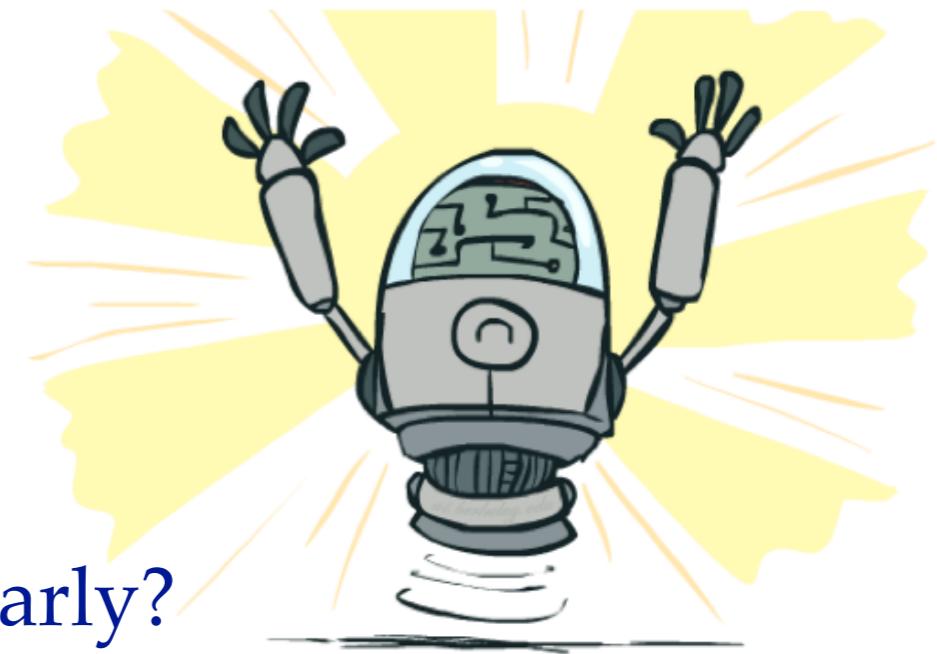

- ❖ General-purpose ideas give huge gains in speed

- ❖ Ordering:

- ❖ Which variable should be assigned next?
 - ❖ In what order should its values be tried?

- ❖ Filtering: Can we detect inevitable failure early?

- ❖ Structure: Can we exploit the problem structure?

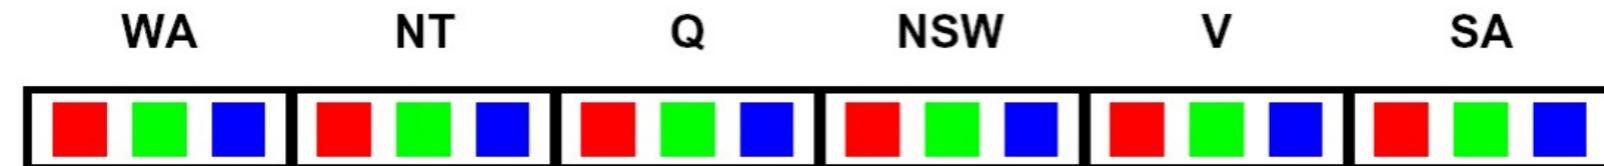

Filtering

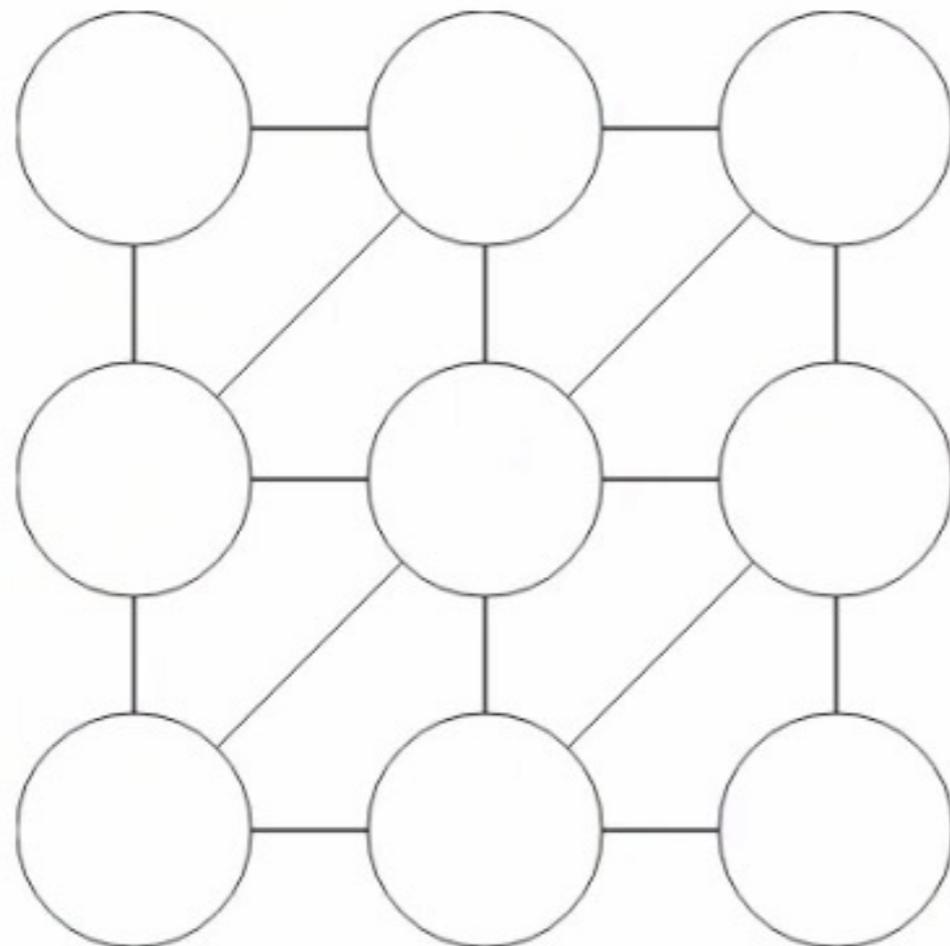

Filtering: Forward Checking

- ❖ Filtering: Keep track of domains for unassigned variables and cross off bad options
- ❖ Forward checking: Cross off values that violate a constraint when added to the existing assignment

Filtering: Constraint Propagation

- Forward checking propagates information from assigned to unassigned variables, but doesn't provide early detection for all failures:

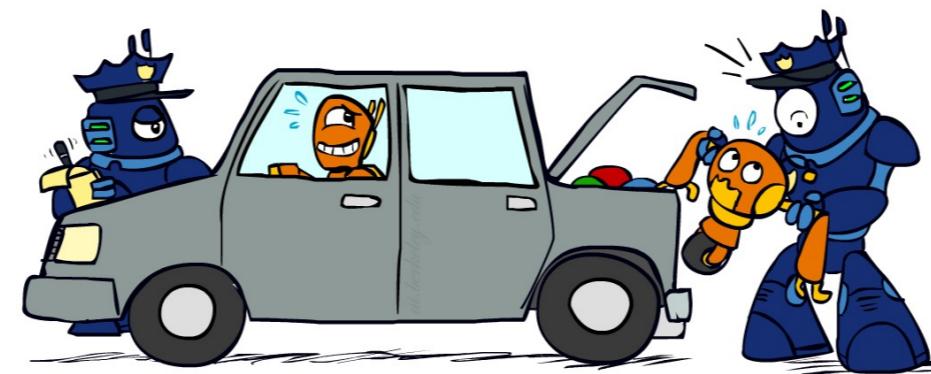

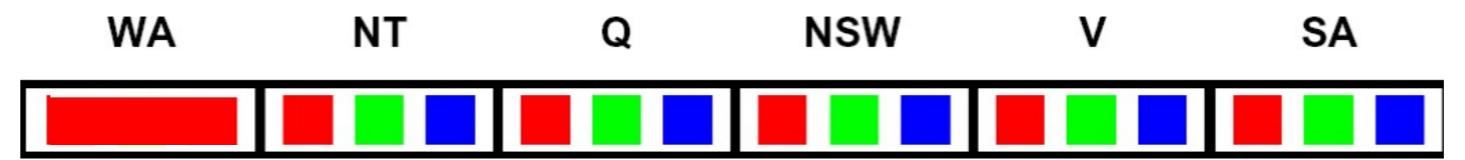

WA	NT	Q	NSW	V	SA
Red	Green	Blue	Red	Green	Blue
Red		Green	Blue	Red	Green
Red		Blue	Green	Red	Blue

- NT and SA cannot both be blue!
- Why didn't we detect this yet?
- Constraint propagation*: reason from constraint to constraint

Consistency of A Single Arc

- An arc $X \rightarrow Y$ is **consistent** iff for *every* x in the tail there is *some* y in the head which could be assigned without violating a constraint

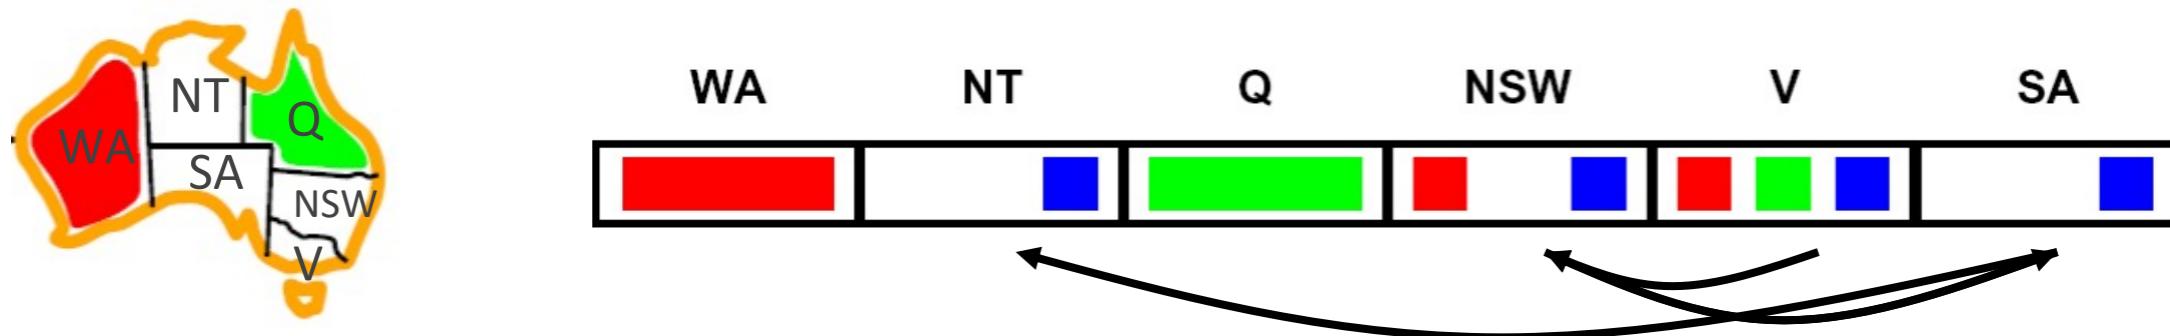

Delete from the tail!

- Forward checking: Enforcing consistency of arcs pointing to each new assignment

Arc Consistency of an Entire CSP

- ❖ A simple form of propagation makes sure **all** arcs are consistent:

- ❖ Important: If X loses a value, neighbors of X need to be rechecked!
- ❖ Arc consistency detects failure earlier than forward checking
- ❖ Can be run as a preprocessor or after each assignment
- ❖ What's the downside of enforcing arc consistency?

*Remember:
Delete from
the tail!*

Enforcing Arc Consistency in a CSP

```
function AC-3( csp) returns the CSP, possibly with reduced domains
  inputs: csp, a binary CSP with variables  $\{X_1, X_2, \dots, X_n\}$ 
  local variables: queue, a queue of arcs, initially all the arcs in csp

  while queue is not empty do
     $(X_i, X_j) \leftarrow \text{REMOVE-FIRST}(\text{queue})$ 
    if REMOVE-INCONSISTENT-VALUES( $X_i, X_j$ ) then
      for each  $X_k$  in NEIGHBORS[ $X_i$ ] do
        add  $(X_k, X_i)$  to queue

  function REMOVE-INCONSISTENT-VALUES( $X_i, X_j$ ) returns true iff succeeds
    removed  $\leftarrow \text{false}$ 
    for each  $x$  in DOMAIN[ $X_i$ ] do
      if no value  $y$  in DOMAIN[ $X_j$ ] allows  $(x, y)$  to satisfy the constraint  $X_i \leftrightarrow X_j$ 
        then delete  $x$  from DOMAIN[ $X_i$ ]; removed  $\leftarrow \text{true}$ 
    return removed
```

- ❖ Runtime: $O(n^2d^3)$, can be reduced to $O(n^2d^2)$
- ❖ ... but detecting all possible future problems is NP-hard – why?

Limitations of Arc Consistency

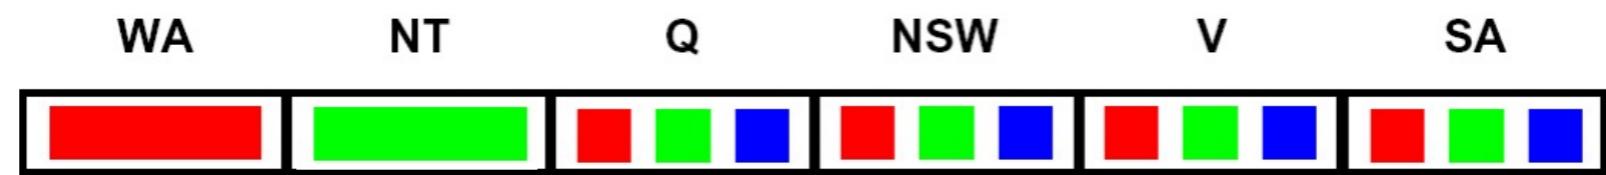

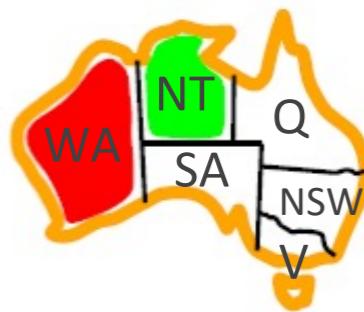

- ❖ After enforcing arc consistency:
 - ❖ Can have one solution left
 - ❖ Can have multiple solutions left
 - ❖ Can have no solutions left (and not know it)
- ❖ Arc consistency still runs inside a backtracking search!

What went wrong here?

Quiz: What is the color of NSW?

- ❖ Run arc consistency on this example:

- ❖ Choose a color
 - ❖ Red
 - ❖ Green
 - ❖ Blue

Video of Demo Coloring – Backtracking with Arc Consistency – Complex Graph

A complex graph for a 3-coloring problem. The graph consists of 18 nodes arranged in three columns of six nodes each. Each node is a circle containing three smaller circles, representing a state with three possible values (blue, red, green). The graph has the following connections:

- The first column has a single vertical connection from the top node to the bottom node.
- The second column has two diagonal connections: one from the top-left node to the bottom-right node, and another from the top-right node to the bottom-left node.
- The third column has two diagonal connections: one from the top-left node to the bottom-right node, and another from the top-right node to the bottom-left node.
- Horizontal connections exist between adjacent nodes in each row.
- Vertical connections exist between adjacent nodes in each column.

Ordering

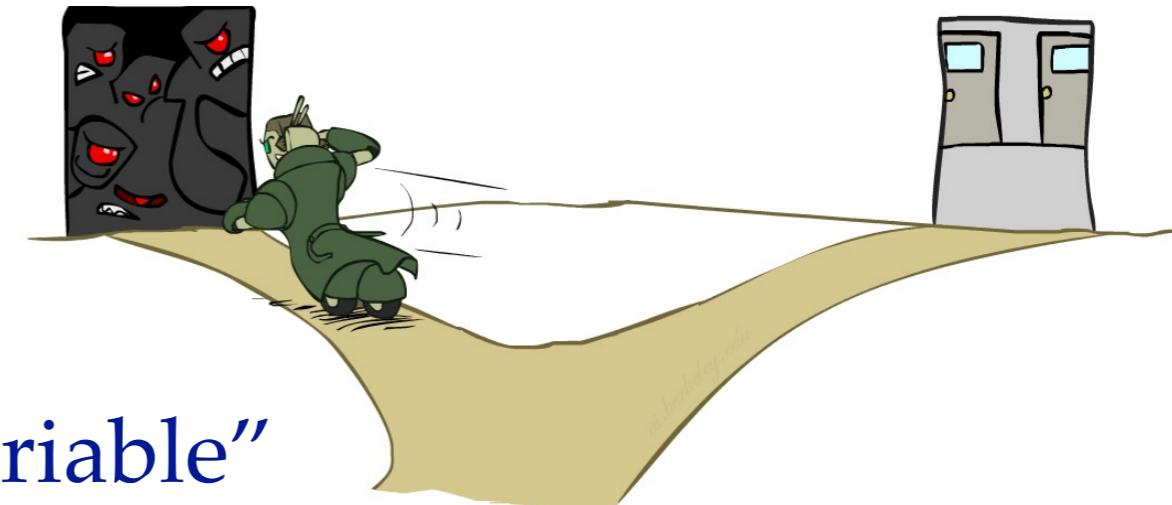

Ordering: Minimum Remaining Values

- ❖ Variable Ordering: Minimum remaining values (MRV):
 - ❖ Choose the variable with the fewest legal left values in its domain

- ❖ Why min rather than max?
- ❖ Also called “most constrained variable”
- ❖ “Fail-fast” ordering

Ordering: Least Constraining Value

- ❖ Value Ordering: Least Constraining Value
 - ❖ Given a choice of variable, choose the *least constraining value*
 - ❖ I.e., the one that rules out the fewest values in the remaining variables
 - ❖ Note that it may take some computation to determine this! (E.g., rerunning filtering)
- ❖ Why least rather than most?
- ❖ Combining these ordering ideas makes 1000 queens feasible
